- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

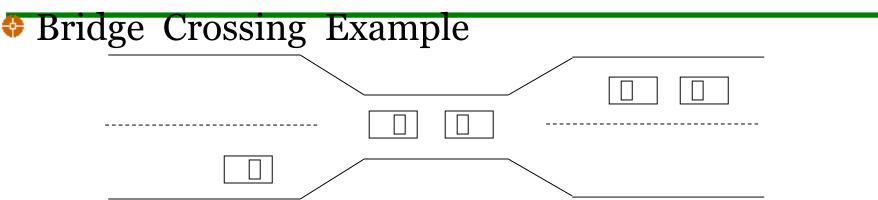

### The Deadlock Problem

- deadlock situation: A set of blocked processes each holding a resource and waiting to acquire a resource held by another process in the set.
- Example 1
  - ✓ System has 2 disk drives
  - ✓ P1 and P2 each hold one disk drive and each needs another one
- Example 2
  - $\checkmark$  semaphores A and B, initialized to 1

```
P0 P1
wait (A); wait (B)
wait (B); wait (A)
```

3/12/2018 BUPTSSE 3

- Traffic only in one direction
- Each section of a bridge can be viewed as a resource
- If a deadlock occurs, it can be resolved if one car backs up (preempt resources and rollback)
- Several cars may have to be backed up if a deadlock occurs
- Starvation is possible
- Note Most OSes do not prevent or deal with deadlocks

- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

## Necessary Conditions

- Deadlock can arise if four conditions hold simultaneously.
  - ✓ Mutual exclusion(互斥):
    - only one process at a time can use a resource.
  - ✓ Hold and wait (持有并等待):
  - a process holding at least one resource is waiting to acquire additional resources held by other processes.
  - ✓ No preemption(不剥夺):
  - a resource can be released only voluntarily by the process holding it, after that process has completed its task.

- Necessary Conditions
  - ✓ Circular wait(循环等待):
  - there exists a set  $\{P_0, P_1, \dots, P_0\}$  of waiting processes such that  $P_0$  is waiting for a resource that is held by  $P_1, P_1$  is waiting for a resource that is held by  $P_2, \dots, P_{n-1}$  is waiting for a resource that is held by  $P_n$ , and  $P_n$  is waiting for a resource that is held by  $P_0$ .

## System Model

- A system consists of a finite number of resources
- The resources are partitioned into several types, each consisting of some number of identical instance.
  - ✓ physical resources: CPU cycles, memory space, I/0 devices
- ✓ logical resources: files, semaphores, and monitors

  System model
  - ✓ Resource types R1 , R2 , . . . , Rm
  - ✓ Each resource type Ri has Wi instances.
  - ✓ Each process utilizes a resource as follows:
    - request: may wait until it can acquire the resource
    - use
    - release

## Resource-Allocation Graph

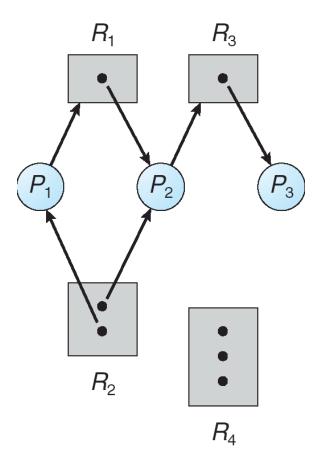

- System resource-allocation graph: A directed graph
  - ✓ A set of vertices V and a set of edges E.
  - ✓ V is partitioned into two types.
  - $P = \{P1, P2, \dots, Pn\}$ , the set consisting of all the processes in the system.
    - : Process
  - $R = \{R1, R2, \dots, Rm\}$ , the set consisting of all resource types in the system.
    - : Resource Type with 4 instances

- Resource-Allocation Graph
  - ✓ E is partitioned into two types.
    - request edge(请求边) directed edge Pi→Rj
  - $P_i$ : Pi requests an instance of Rj
    - assignment edge(分配边) directed edge Rj→Pi
  - Pi : Pi is holding an instance of Rj

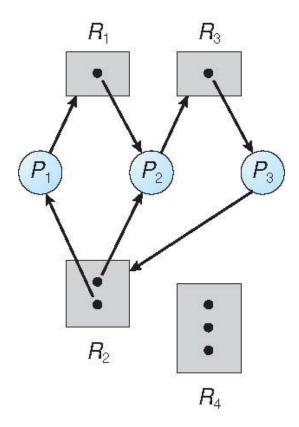

Example of a Resource Allocation Graph

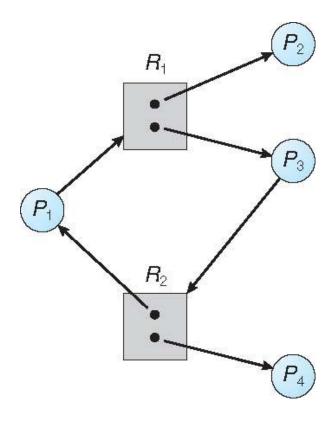

Example of a resource Allocation Graph With A

Deadlock

Graph With A Cycle But No Deadlock

#### Basic Facts

- If graph contains no cycles  $\Rightarrow$  no deadlock.
- If graph contains a cycle ⇒
  - ✓ if only one instance per resource type, then deadlock.
  - ✓ if several instances per resource type, possibility of deadlock.

# Methods for Handling Deadlocks

- Methods for Handling Deadlocks
  - Ensure that the system will never enter a deadlock state.
    - ✓ Deadlock prevention
    - ✓ Deadlock avoidance
  - Allow the system to enter a deadlock state and then recover.
    - ✓ Deadlock detection and recovery from deadlock
  - Ignore the problem and pretend that deadlocks never occur in the system; used by most operating systems, including UNIX.

- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

- Deadlock prevention provides a set of methods for ensuring that at least one of the necessary conditions cannot hold.
- Restrain the ways request can be made.
- Mutual Exclusion
  - not required for sharable resources (read-only files); must hold for nonsharable resources. (printer)
  - In general, therefore, we cannot deny the mutual-exclusion condition

#### Hold and Wait

- must guarantee that whenever a process requests a resource, it does not hold any other resources.
  - ✓ Require process to request and be allocated all its resources before it begins execution, or
  - ✓ allow process to request resources only when the process has none.
- Disadvantage:
  - ✓ Low resource utilization;
  - ✓ starvation possible.

## No Preemption

- If a process that is holding some resources, requests another resource that cannot be immediately allocated to it, then all resources currently being held are preempted.
  - ✓ Preempted resources are added to the list of resources for which the process is waiting.
  - ✓ Process will be restarted only when it can regain its old resources, as well as the new ones that it is requesting.
- preempt the desired resources from the waiting process and allocate them to the requesting process
  - ✓ if the resource are neither available nor held by a waiting process, the requesting process must wait. While waiting, some of its resources may be preempted by other requesting process
  - ✓ a process can be restarted only when it is allocated the new resources it is requesting and recovers any resources that were preempted.

#### Circular Wait

- impose a total ordering of all resource types, and require that each process requests resources in an increasing order of enumeration.
  - ✓ always in an increasing order
  - ✓ may release some higher ordered resource before requesting lower ordered resource

- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

Executing a deadlock avoidance algorithm to ensure there can never be a circular-wait condition.

Banker's Algorithm

- Requires that the system has some additional a priori information available.
  - Simplest and most useful model requires that each process declare the maximum number of resources of each type that it may need.
  - The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition.
  - Resource—allocation state is defined by the number of available and allocated resources, and the maximum demands of the processes.

## An Example

- Total resources 12; 3 processes
- Snapshot at time t<sub>0</sub>

	Max	Allocation	Need	Available
P1	10	5	5	3
P2	4	2	2	
P3	9	2	7	

## ◆ Safe State (安全状态)

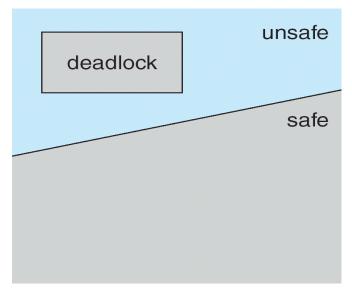

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state.
- System is in safe state if there exists a safe sequence <P1, P2, ..., Pn> of all the processes
- Sequence <P1, P2, ..., Pn> is safe if for each Pi, the resources that Pi can still request can be satisfied by currently available resources + resources held by all the Pj, with j < i
  - ✓ That is:
  - ✓ If Pi resource needs are not immediately available, then Pi can wait until all Pj have finished.
  - ✓ When Pj is finished, Pi can obtain needed resources, execute, return allocated resources, and terminate.
  - ✓ When Pi terminates, Pi +1 can obtain its needed resources, and so on.

3/12/2018 BUPTSSE 25

#### Basic Facts

- If a system is in safe state ⇒ no deadlocks
- If a system is in unsafe state ⇒ possibility of deadlock
- Avoidance  $\Rightarrow$  ensure that a system will never enter an unsafe state.

### Avoidance algorithms

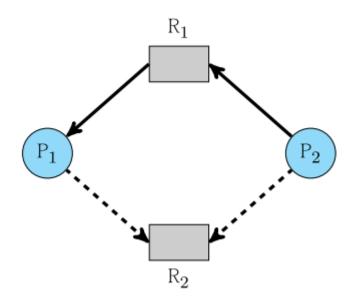

- Single instance of a resource type
  - ✓ Use a resource—allocation graph
- Multiple instances of a resource type
  - ✓ Use the banker's algorithm

- Resource-Allocation Graph Scheme
  - Resource-Allocation Graph
    - ✓ Claim edge(需求边) Pi → Rj indicated that process Pj may request resource Rj; represented by a dashed line
    - ✓ Claim edge converts to request edge when a process requests a resource
    - ✓ Request edge converted to an assignment edge when the resource is allocated to the process
    - ✓ When a resource is released by a process, assignment edge reconverts to a claim edge
    - ✓ Resources must be claimed a priori in the system

- Resource-Allocation Graph Scheme
  - Example: Safe State

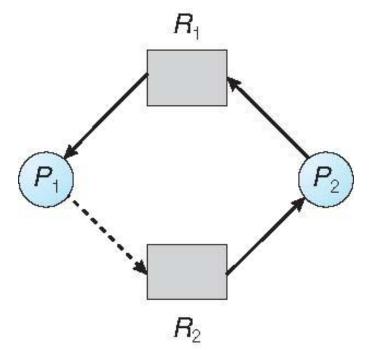

safe sequence: < P 1, P 2 >

Resource-Allocation Graph Scheme

Example: Unsafe State In Resource-Allocation

Graph

Unsafe State In Resource-Allocation Graph

- \* Resource-Allocation Graph Scheme
  - Resource-Allocation Graph Algorithm
    - ✓ Suppose that process Pi requests a resource Rj
    - ✓ The request can be granted only if converting the request edge to an assignment edge does not result in the formation of a cycle in the resource allocation graph

- ⇔ Banker's Algorithm (银行家算法)
  - Multiple instances
  - Each process must a priori claim maximum use
  - When a process requests a resource it may have to wait
  - When a process gets all its resources it must return them in a finite amount of time
- Data structures
- safety algorithm
- resource-request algorithm

## | Deadlock Avoidance (死锁避免)

#### Data structures

- Let n = number of processes, and m = number of resources types.
  - ✓ Available: Vector of length m. If available [j] = k, there are k instances of resource type Rj available
  - ✓ Max: n x m matrix. If Max [i, j] = k, then process Pi may request at most k instances of resource type Rj
  - ✓ Allocation: n x m matrix. If Allocation[i, j] = k then Pi is currently allocated k instances of Rj
  - ✓ Need: n x m matrix. If Need[i, j] = k, then Pi may need k more instances of Rj to complete its task

Need [i, j] = Max[i, j] - Allocation <math>[i, j]

## Deadlock Avoidance (死锁避免)

### Safety Algorithm

1. Let Work and Finish be vectors of length m and n, respectively. Initialize:

Work = Available Finish [i] = false for  $i = 0, 1, \dots, n-1$ 

- 2. Find an i such that both:
  - (a) Finish [i] = false
  - (b) Need<sub>i</sub>  $\leq$  Work

If no such i exists, go to step 4

- 3. Work = Work + Allocationi Finish[i] = true go to step 2
- 4. If Finish [i] == true for all i, then the system is in a safe state

#### \* Resource-Request Algorithm for Process Pi

 $Request = request \ vector \ for \ process \ P_i$ 

3/12/2018

If  $Request_i[j] = k$  then process  $P_i$  wants k instances of resource type  $R_i$ 

- 1. If  $Request_i \leq Need_i$  go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim
- 2. If  $Request_i \le Available$ , go to step 3. Otherwise  $P_i$  must wait, since resources are not available
- 3. Pretend to allocate requested resources to  $P_i$  by modifying the state as follows:

```
Available = Available - Request;
Allocation<sub>i</sub> = Allocation<sub>i</sub> + Request<sub>i</sub>;
```

 $Need_i = Need_i - Request_i$ 

If safe ⇒ the resources are allocated to Pi

If unsafe ⇒ Pi must wait, and the old resource-allocation state is restored

BUPTSE

35

- Example of Banker's Algorithm
- 5 processes P0 through P4;
- 3 resource types:

A (10 instances), B (5instances), and C (7 instances)

Snapshot at time To:

<b>•</b>		Allocation	Max	Available
		ABC	ABC	ABC
	P0	010	7 <i>5 3</i>	332
	P1	200	322	
	P2	302	902	
	P3	211	222	
	P4	002	433	

- Example of Banker' s Algorithm
- The content of the matrix Need is defined to be Max Allocation

	Need	
	ABC	
P0	7 4 3	
P1	122	
P2	600	
P3	011	
P4	431	

The system is in a safe state since the sequence < P1, P3, P4, P2, P0> satisfies safety criteria

# Example: P1 Request (1,0,2)

Check that Request ≤ Available (that is, (1,0,2) ≤ (3,3,2) ⇒ true)

	<u>Allocation</u>	<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	010	7 4 3	3 3 2 - 2 3 0
$P_1$	2 0 0 → 3 0 2	1 2 2	20
$P_2$	3 0 1	600	
$P_3$	211	011	
$P_4$	002	4 3 1	

- Executing safety algorithm shows that sequence  $< P_1, P_3, P_4, P_0, P_2 >$  satisfies safety requirement
- Can request for (3,3,0) by  $P_4$  be granted?
- Can request for (0,2,0) by  $P_0$  be granted?

- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

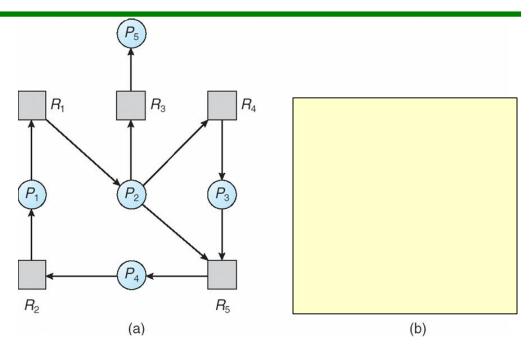

- Allow system to enter deadlock state
  - Detection algorithm
    - ✓ single instance
    - ✓ several instances
  - Recovery scheme
    - ✓ Process termination
    - ✓ Resource preemption

# Deadlock Detection (死锁检测)

- Maintain wait-for graph
  - Nodes are processes
  - Pi  $\rightarrow$  Pj if Pi is waiting for Pj

Resource-Allocation Graph

Corresponding wait-for graph

41

Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock

# Several Instances of a Resource Type

#### ■ Data structures:

- ✓ Available: A vector of length m indicates the number of available resources of each type.
- ✓ Allocation: An n x m matrix defines the number of resources of each type currently allocated to each process.
- ✓ Request: An n x m matrix indicates the current request of each process. If Request[i][j] = k, then process Pi is requesting k more instances of resource type Rj.

- 1. Let Work and Finish be vectors of length m and n, respectively Initialize:
  - (a) Work = Available
  - (b) For i = 1,2, ..., n, if  $Allocation_i \neq 0$ , then Finish[i] = false; otherwise, Finish[i] = true
- 2. Find an index *i* such that both:
  - (a) Finish[i] == false
  - (b)  $Request_i \leq Work$

If no such i exists, go to step 4

- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If Finish[i] == false, for some i,  $1 \le i \le n$ , then the system is in deadlock state. Moreover, if Finish[i] == false, then  $P_i$  is deadlocked

### Example of Detection Algorithm

- Five processes  $P_0 P_4$ ;
- three resource types
  A (7 instances), B (2 instances), and C (6 instances)
- Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	010	000	000
$P_1$	200	202	
$P_2$	3 0 3	000	
$P_3$	2 1 1	100	
$P_4$	002	002	

Sequence  $\langle P_0, P_2, P_3, P_1, P_4 \rangle$  will result in Finish[i] = true for all i BUPTSSE

## Example of Detection Algorithm

■ If  $P_2$  requests an additional instance of type C

- State of system?
  - Can reclaim resources held by process  $P_0$ , but insufficient resources to fulfill other processes requests
  - Deadlock exists, consisting of processes P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>, and P<sub>4</sub>

- Example of Detection Algorithm
  - ✓ When, and how often, to invoke the algorithm, depends on:
  - How often a deadlock is likely to occur?
  - How many processes will need to be rolled back?
  - ✓ If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes "caused" the deadlock.

- The Deadlock Problem
- Deadlock Characterization
- Methods for Handling Deadlocks
- Deadlock Prevention
- Deadlock Avoidance
- Deadlock Detection
- Recovery from Deadlock

## Process Termination

- ✓ Abort all deadlocked processes
- ✓ Abort one process at a time until the deadlock cycle is eliminated
- ✓ To minimize cost: In which order should we choose to abort?
- -Priority of the process
- -How long process has computed, and how much longer to completion
- -Resources the process has used
- -Resources process needs to complete
- -How many processes will need to be terminated
- -Is process interactive or batch?

- Resource Preemption
  - Three issues need to be addressed:
    - ✓ Selecting a victim minimize cost
    - ✓ Rollback return to some safe state, restart process for that state
    - ✓ Starvation same process may always be picked as victim, include number of rollback in cost factor
